

# Lesson 11: More About Similar Triangles

#### **Student Outcomes**

- Students present informal arguments as to whether or not two triangles are similar.
- Students practice finding lengths of corresponding sides of similar triangles.

#### Lesson Notes

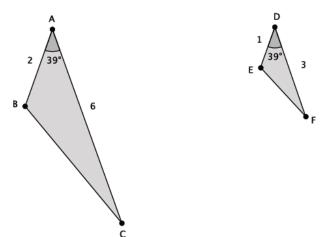

This lesson synthesizes the knowledge gained thus far in Module 3. Students use what they know about dilation, congruence, the Fundamental Theorem of Similarity (FTS), and the angle-angle (AA) criterion to determine if two triangles are similar. In the first two examples, students use informal arguments to decide if a pair of triangles are similar. To do so, they look for pairs of corresponding angles that are equal (wanting to use the AA criterion). When they realize that information is not given, they compare lengths of corresponding sides to see if the sides could be dilations with the same scale factor. After a dilation and congruence are performed, students see that a pair of triangles are similar (or not) and then continue to give more proof as to why they must be. For example, by FTS, a specific pair of lines are parallel, and the corresponding angles cut by a transversal must be equal; therefore, we can use AA criterion to state that two triangles are similar. Once students know how to determine whether two triangles are similar, they apply this knowledge to finding lengths of segments of triangles that are unknown in Examples 3–5.

#### Classwork

**MP.1** 

#### Example 1 (6 minutes)

Given the information provided, is  $\triangle ABC \sim \triangle DEF$ ? (Give students a minute or two to discuss with a partner.)

Students will likely say that they cannot tell if the triangles are similar because there is only information for one angle provided. In the previous lesson, students could determine if two triangles were similar using AA criterion.

Date:

• What if we combined our knowledge of dilation and similarity? That is, we know we can translate  $\triangle ABC$  so that the measure of  $\angle A$  is equal in measure to  $\angle D$ . Then our picture would look like this:

Lesson 11

- Can we tell if the triangles are similar now?
  - We still do not have information about the angles, but we can use what we know about dilation and FTS to find out if side EF is parallel to side BC. If they are, then  $\triangle ABC \sim \triangle DEF$  because the corresponding angles of parallel lines are equal.
- We do not have the information we need about corresponding angles. So let's examine the information we are provided. Compare the given side lengths to see if the ratios of corresponding sides are equal:
  - Is  $\frac{|AE|}{|AB|} = \frac{|AF|}{|AC|}$ ? That's the same as asking if  $\frac{1}{2} = \frac{3}{6}$ . Since the ratios of corresponding sides are equal, then there exists a dilation from center A with scale factor  $r = \frac{1}{2}$  that maps  $\triangle ABC$  to  $\triangle DEF$ . Since the ratios of corresponding sides are equal, then by FTS, we know side EF is parallel to side BC and the corresponding angles of the parallel lines are also equal in measure.
- This example illustrates another way for us to determine if two triangles are similar. That is, if they have one pair of equal corresponding angles, and the ratio of corresponding sides (along each side of the given angle) are equal, then the triangles are similar.

### Example 2 (4 minutes)

Given the information provided, is  $\triangle ABC \sim \triangle AB'C'$ ? Explain. (Give students a minute or two to discuss with a partner.)

If students say that the triangles are not similar because lines BC and B'C' are not parallel, ask them how they know this. If they say, "They don't look parallel", tell students that the way they look is not good enough. They must prove mathematically that the lines are not parallel. Therefore, the following response is more legitimate.

- We do not have information about two pairs of corresponding angles, so we will need to examine the ratios of corresponding side lengths. If the ratios are equal, then the triangles are similar.
- If the ratios of the corresponding sides are equal, it means that the lengths were dilated by the same scale factor. Write the ratios of the corresponding sides.
  - The ratios of corresponding sides are  $\frac{|AC'|}{|AC|} = \frac{|AB'|}{|AB|}$ .
- Does  $\frac{|AC'|}{|AC|} = \frac{|AB'|}{|AB|}$ ? That is the same as asking if  $\frac{7.1}{2.7}$  and  $\frac{8}{4.9}$  are equivalent fractions. One possible way of verifying if the fractions are equal is by multiplying the numerator of each fraction by the denominator of the other. If the products are equal, then we know the fractions are equivalent.
  - The products are 34.79 and 21.6. Since  $34.79 \neq 21.6$ , the fractions are not equivalent, and the triangles are not similar.

#### Example 3 (4 minutes)

Given that  $\triangle ABC \sim \triangle AB'C'$ , could we determine the length of AB'? What does it mean to say that  $\triangle ABC \sim \triangle AB'C'$ ? (Give students a minute or two to discuss with a partner.)

- It means that the measures of corresponding angles are equal; the ratios of corresponding sides are equal, i.e.,  $\frac{|AC'|}{|AC|} = \frac{|AB'|}{|AB|} = \frac{|B'C'|}{|BC|}$ , and lines BC and B'C' are parallel.
- How can we use what we know about similar triangles to determine the length of *AB*'?
  - The lengths of corresponding sides are supposed to be equal in ratio:  $\frac{|AC'|}{|AC|} = \frac{|AB'|}{|AB|}$  is the same as  $\frac{15}{5} = \frac{|AB'|}{2}$ .
- Since we know that for equivalent fractions, when we multiply the numerator of each fraction by the denominator of the other fraction, the products are equal, we can use that fact to find the length of side *AB'*. Let *x* represent the length of *AB'*; then  $\frac{15}{5} = \frac{|AB'|}{2}$  is the same as  $\frac{15}{5} = \frac{x}{2}$ . Equivalently, we get 30 = 5x. The value of *x* that makes the statement true is x = 6. Therefore, the length of side *AB'* is 6.

# J

# Example 4 (4 minutes)

• If we suppose XY is parallel to X'Y', can we use the information provided to determine if  $\triangle OXY \sim \triangle OX'Y'$ ? Explain. (Give students a minute or two to discuss with a partner.)

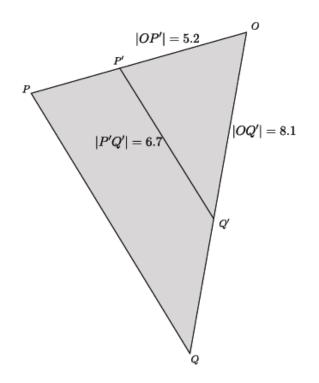

- Since we assume XY||X'Y', then we know we have similar triangles because each triangle shares  $\angle O$ and the corresponding angles are congruent:  $\angle OXY \cong \angle OX'Y'$ , and  $\angle OYX \cong \angle OY'X'$ . By the AA criterion, we can conclude that  $\triangle OXY \sim \triangle OX'Y'$ .
- Now that we know the triangles are similar, can we determine the length of side OX'? Explain.
  - By the converse of FTS, since we are given parallel lines and the lengths of the corresponding sides XY and X'Y', we can write the ratio that represents the scale factor and compute using the fact that cross products must be equal to determine the length of side OX'.
- Write the ratio for the known side lengths *XY* and *X*'*Y*' and the ratio that would contain the side length we are looking for. Then use the cross products to find the length of side *OX*'.
  - $\frac{|X'Y'|}{|XY|} = \frac{|OX'|}{|OX|}$  is the same as  $\frac{6.25}{5} = \frac{|OX'|}{4}$ . Let z represent the length of side OX'. Then we have  $\frac{6.25}{5} = \frac{z}{4}$  or equivalently, 5z = 25 and z = 5. Therefore, the length of side OX' is 5.
- Now find the length of OY'.
  - $\frac{|X'Y'|}{|XY|} = \frac{|OY'|}{|OY|}$  is the same as  $\frac{6.25}{5} = \frac{|OY'|}{6}$ . Let w represent the length of side OY'. Then we have  $\frac{6.25}{5} = \frac{w}{6}$  or equivalently, 5w = 37.5 and w = 7.5. Therefore, the length of side OY' is 7.5.

#### **Example 5 (3 minutes)**

Given the information provided, can you determine if  $\triangle OPQ \sim \triangle OP'Q'$ ? Explain. (Give students a minute or two to discuss with a partner.)

■ No, in order to determine if  $\triangle OPQ \sim \triangle OP'Q'$  we need information about two pairs of corresponding angles. As is, we only know that the two triangles have one equal angle, the common angle at 0. We would have corresponding angles that were equal if we knew that sides  $PQ \parallel P'Q'$ . Our other option is to compare the ratio of the sides that comprise the common angle. However, we do not have information about the lengths sides OP or OQ. For that reason, we cannot determine whether or not  $\triangle OPQ \sim \triangle OP'Q'$ .

# Closing (5 minutes)

Summarize, or ask students to summarize, the main points from the lesson.

- We know that if we are given just one pair of corresponding angles as equal, we can use the side lengths along the given angle to determine if triangles are in fact similar.
- If we know that we are given similar triangles, then we can use the fact that ratios of corresponding sides are equal to find any missing measurements.

1. In the diagram below, you have  $\triangle ABC$  and  $\triangle A'B'C'$ . Based on the information given, is  $\triangle ABC \sim \triangle A'B'C'$ ? Explain.

In the diagram below,  $\triangle ABC \sim \triangle DEF$ . Use the information to answer parts (a)–(b). 2.

- Determine the length of side *AB*. Show work that leads to your answer. a.
- b. Determine the length of side *DF*. Show work that leads to your answer.
